EVOLUTIONARY COMPUTATION

Lecture Notes_2

Genetic Representation and Search Operators

Topics Covered

Topics

- Genetic Representation: Binary, real-valued, and tree-based encodings
- Search Operators: Mutation, crossover

1. Introduction to Genetic Representation and Search Operators

Genetic Algorithms (GAs) are optimization techniques inspired by the process of natural evolution. They utilize populations of potential solutions and evolve them over iterations to find optimal or near-optimal solutions to complex problems. Central to GAs are two key concepts: **genetic representation** (how solutions are encoded) and **search operators** (how solutions are manipulated).

2. Genetic Representation

The choice of genetic representation affects how solutions are encoded and how operators like mutation and crossover are applied. The main types of genetic representations are:

2.1 Binary Encoding

- **Definition:** Solutions are represented as binary strings (sequences of 0s and 1s).
- **Example:** For a problem requiring four variables, a solution might look like 1010.
- **Advantages:**
  - Simple and widely used.
  - Effective for combinatorial problems.
- **Limitations:**
  - Can be inefficient for problems with real-valued parameters.

2.2 Real-Valued Encoding

- **Definition:** Solutions are represented as vectors of real numbers.
- **Example:** For a problem with three variables, a solution might look like [2.5, -1.3, 4.7].
- **Advantages:**
  - More natural representation for continuous problems.
  - Avoids the need for binary-to-real conversion.

- **Limitations:**
  - Search operators can be more complex.

2.3 Tree-Based Encoding

- **Definition:** Solutions are represented as hierarchical tree structures, often used in Genetic Programming (GP).
- **Example:** A tree might represent a mathematical expression such as:

  (x + 2) * (y - 3).

- **Advantages:**
  - Flexible and powerful for problems like symbolic regression or program synthesis.
  - Represents variable-length solutions.
- **Limitations:**
  - Requires specialized crossover and mutation operators.
  - Can be computationally expensive.

3. Search Operators

Search operators are responsible for generating new solutions by modifying or combining existing ones. The two primary types are **mutation** and **crossover**.

3.1 Mutation

- **Definition:** Introduces random changes to individual solutions to maintain diversity in the population.
- **Types of Mutation:**
  - **Binary Mutation:** Flipping bits in binary strings (e.g., 1010 becomes 1000).
  - **Real-Valued Mutation:** Adding small random perturbations to real-valued vectors (e.g., [2.5, -1.3, 4.7] becomes [2.7, -1.1, 4.8]).
  - **Tree Mutation:** Replacing or modifying a subtree in tree-based encodings.
- **Impact:**
  - Prevents premature convergence.
  - Maintains genetic diversity.

3.2 Crossover

- **Definition:** Combines information from two parent solutions to produce offspring.
- **Types of Crossover:**
  - **Single-Point Crossover:** A single crossover point is selected, and segments are swapped between parents.

        - Example: Parent1: 1010 and Parent2: 1101 → Offspring: 1011 and 1100.
    - **Two-Point Crossover:** Two points are selected, and the segments between them are swapped.
    - **Uniform Crossover:** Each bit is independently chosen from one of the parents with equal probability.
    - **Arithmetic Crossover (for real-valued):** Produces offspring by weighted averaging of parents.
        - Example: Parent1: [2.5, -1.3, 4.7] and Parent2: [3.0, -1.0, 4.0] → Offspring: [2.75, -1.15, 4.35].
    - **Tree Crossover:** Subtrees are exchanged between parent trees.
- **Impact:**
    - Exploits existing genetic material.
    - Facilitates the mixing of good traits.

4. Use Cases

1. **Binary Encoding:** Solving a knapsack problem.
2. **Real-Valued Encoding:** Optimizing a continuous function (e.g., minimizing a cost function).
3. **Tree-Based Encoding:** Symbolic regression or program synthesis tasks.
4. **Mutation:** Diversifying solutions in a constrained optimization problem.
5. **Crossover:** Improving convergence in a genetic search for scheduling problems.

5. Lab Activities

Activity 1: Implement Binary Representation

- Write a Python program to represent solutions as binary strings.
- Apply single-point crossover and bit-flip mutation.

Activity 2: Explore Real-Valued Representation

- Use a library like NumPy to represent and manipulate real-valued solutions.
- Apply arithmetic crossover and Gaussian mutation.

Activity 3: Tree-Based Representation

- Implement tree-based solutions for a symbolic regression problem using libraries like DEAP.
- Perform subtree mutation and crossover.

6. Extra Activities

1. **Comparative Study:** Implement all three representations and compare their performance on the same problem.

2. **Visualization:** Plot the evolution of solutions over generations using Matplotlib.
3. **Hybrid Approaches:** Combine binary and real-valued representations for mixed-variable optimization problems.

7. Scenario-Based Questions

1. **Scenario:** Your GA is stuck in a local optimum. Suggest modifications to the mutation operator to escape.
2. **Scenario:** You observe that diversity in the population is decreasing. How can you use crossover to address this?

8. Discussion Questions

1. Why might binary encoding be less effective for problems with continuous variables?
2. What are the trade-offs between mutation and crossover in maintaining diversity and convergence?
3. How can tree-based representations be optimized for computational efficiency?

9. Case Analysis Questions

1. Analyze the suitability of genetic representations for the Traveling Salesman Problem.
2. Evaluate the effectiveness of uniform crossover in maintaining population diversity.
3. Discuss the role of mutation in preventing premature convergence in real-valued optimization problems.

10. Sentence Questions

1. Describe the key difference between binary and real-valued representations.
2. Explain why mutation is crucial for genetic algorithms.
3. What is the primary purpose of crossover in GAs?

11. Practice Questions

1. Implement a GA with binary representation and test it on the OneMax problem.
2. Create a GA for a function optimization problem using real-valued representation.
3. Experiment with different mutation rates and observe their impact on GA performance.

Solved Problems with Workings: Genetic Representation and Search Operators

1. Genetic Representation

Problem 1: Binary Encoding

Task: Represent a solution to the following problem using binary encoding: Maximize $f(x) = x^2$ where $x \in [0, 15]$.

Solution:

1. **Representation**:
   - Use a 4-bit binary string to encode x (since $2^4 = 16$ covers the range $[0, 15]$).
   - Each binary string represents an integer value of x.
2. **Example Encoding**:
   - $x = 0 \rightarrow 0000$
   - $x = 5 \rightarrow 0101$
   - $x = 15 \rightarrow 1111$
3. **Evaluate Fitness**:
   - For $x = 5$, $f(5) = 5^2 = 25$.
   - For $x = 15$, $f(15) = 15^2 = 225$.

Problem 2: Real-Valued Encoding

Task: Represent $x \in [0, 10]$ as a real-valued encoding for optimizing $f(x) = \sin(x) + \cos(x)$.

Solution:

1. **Representation**:
   - Use a floating-point number to represent x.
   - Precision can be specified, e.g., x to 2 decimal places.
2. **Example Encoding**:
   - $x = 3.14$, $x = 7.62$.
3. **Evaluate Fitness**:
   - For $x = 3.14$, $f(3.14) = \sin(3.14) + \cos(3.14) \approx -0.0016$.
   - For $x = 7.62$, $f(7.62) = \sin(7.62) + \cos(7.62) \approx 0.343$.

Problem 3: Tree-Based Encoding

Task: Represent a mathematical expression for $f(x, y) = x^2 + y^2$ using tree-based encoding.

Solution:

1. Representation:
   - Use a tree where:
     - Internal nodes represent operators ($+, -, *, /$).
     - Leaf nodes represent variables (x, y) or constants.
2. Example Encoding:

```markdown
        +
       / \
      *   *
     / \ / \
    x  x y  y
```

3. Evaluate Fitness:
   - For $x = 2, y = 3$, $f(2, 3) = 2^2 + 3^2 = 4 + 9 = 13$.

2. Search Operators

Problem 4: Mutation (Binary Encoding)

Task: Apply bit-flip mutation to the binary string 1011.

Solution:

1. Choose Mutation Point:
   - Assume mutation occurs at position 2 (counting from the left).
2. Perform Mutation:
   - Original string: 1011.
   - Mutated string: 1111 (flip the second bit).

Problem 5: Mutation (Real-Valued Encoding)

Task: Apply mutation to $x = 7.62$ with a mutation range of $[-0.5, 0.5]$.

Solution:

1. **Add Random Perturbation**:
   - Assume a random value of $+0.3$ is chosen.
2. **Perform Mutation**:
   - Original value: $x = 7.62$.
   - Mutated value: $x = 7.62 + 0.3 = 7.92$.

Problem 6: Crossover (Binary Encoding)

Task: Perform one-point crossover on $P_1 = 1010$ and $P_2 = 1100$.

Solution:

1. **Choose Crossover Point**:
   - Assume the crossover point is after the second bit.
2. **Perform Crossover**:
   - $P_1 = 1010$, $P_2 = 1100$.
   - Offspring:
     - $O_1 = 1010 \,|\, 00 = 1000$.
     - $O_2 = 1100 \,|\, 10 = 1110$.

Problem 7: Crossover (Real-Valued Encoding)

Task: Perform arithmetic crossover on $P_1 = 2.5$ and $P_2 = 4.5$.

Solution:

1. **Formula**:
   - $O_1 = \alpha \cdot P_1 + (1 - \alpha) \cdot P_2$,
   - $O_2 = (1 - \alpha) \cdot P_1 + \alpha \cdot P_2$,
   - where $\alpha \in [0, 1]$.
2. **Example**:
   - Assume $\alpha = 0.6$.
   - $O_1 = 0.6 \cdot 2.5 + 0.4 \cdot 4.5 = 3.5$,
   - $O_2 = 0.4 \cdot 2.5 + 0.6 \cdot 4.5 = 3.5$.

Problem 8: Crossover (Tree-Based Encoding)

Task: Perform subtree crossover on two parent trees.

Solution:

1. **Parent Trees**:

```javascript
P_1:            +          P_2:           *
               / \                      /   \
              x   *                    +     y
                 / \                  / \
                y   z                x   z
```

2. **Choose Subtrees**:
   - Select the subtree rooted at $*$ in P_1,
   - Select the subtree rooted at $+$ in P_2.
3. **Swap Subtrees**:

```javascript
O_1:            +          O_2:           *
               / \                      /   \
              x   +                    *     y
                 / \                  / \
                x   z                y   z
```
